

Does the switch support dual-network access

Overview

Dual Device Mode is a powerful feature found in certain PoE (Power over Ethernet) and Ethernet switches that enables them to simultaneously support two different networks or devices while ensuring complete network isolation. Cisco Catalyst™ 9300 Series Switches are Cisco's lead stackable enterprise access switching platform and, as part of the Catalyst 9000 family, are built to transform your network to handle a hybrid world where the workplace is anywhere, endpoints could be anything, and applications are hosted all. A network switch (also called switching hub, bridging hub, Ethernet switch, and—by the IEEE — MAC bridge) is networking hardware that connects devices on a computer network by using packet switching to receive and forward data to the destination device. This connection option can be helpful for both single-firewall and dual-firewall configurations using HA Pro mode. This innovative capability offers several advantages to network. In this session, Our focus will be to learn about the existing and new High Availability features present on the Catalyst 9k Switches. In the end we will see how these features can be leveraged.
